

CADD – Computer aided drug design

Course structure

- 5 Theoretical classes (2h each)
- 5 Practical classes (2h each)
- Topics:
 - Introduction to Computational Drug Design
 - Molecular representations, formats and descriptors
 - Molecular similarity, fingerprinting and scaffolds
 - Programmatic access to Chemical Databases (ChEMBL, PubChem)
 - Molecular mechanics, energy minimization and molecular dynamics
 - Molecular docking and virtual screening
 - Machine Learning in Drug Design
- Practical classes use *Colab Notebooks*, offering free and online computational capacity

Introduction to Drug Design and Computational Approaches

Drug design and CADD

- **What is Drug Design?**

Systematic process of identifying molecules with therapeutic potential, through a combination of biological, chemical and computational techniques

- **What is Computer-Aided Drug Design (CADD)?**

Drug design process that uses computational techniques, tools and models to facilitate the discovery of new drugs.

Drug discover *versus* development

- **Drug discovery** - all the experimentation and studies designed to move a program from the initial identification of a biological target and associated disease state to the identification of single compound with the potential to be clinically relevant.
- **Drug Development** - typically begins once a single compound has been identified, which is then progressed through various studies designed to support its approval for sale by the appropriate regulatory bodies

Rational drug design

- **Rational drug design** – discovery of new drugs based on the knowledge of structure and mechanism rather than trial and error
- **Empirical or “irrational” drug discovery** – random screening of natural compounds or fortuitous observation of new effect (*serendipity*)

- Examples:

- Penicilin (fortuitous) :

- Imatinib (rational drug design)

Disease -> Mechanism -> Target -> Drug

How are new drugs found ?

- Natural products (e.g. Aspirin)
- Screening assays
- Synthetic chemistry
- Combinatorial chemistry
- Similarity with known drugs (“Me too” drugs)
- Re-purposing (searching known drugs for a new effect)
- Serendipity:
 - Drugs found by chance (e.g. Penicillin)
 - Unforeseen side-effect of a drug or candidate

Drugs found by different methods

Simvastatin
("me too")

Aspirin
(natural product)

Maraviroc
(HTS assay)

Penicillin
(serendipity)

Sildenafil
(repurposing)

LLP2A-Ale
(combinatorial chemistry)

The challenge of drug discovery and design

- The task of discovering new drugs is hard, expensive, lengthy and dependent on a very large number of scientific disciplines, techniques and expertise.
- Millions of compounds may have to be screened in activity tests to select but a few candidates (hits), of which only a few show promise as drug candidate (leads).
- Lengthy and thorough clinical testing in both animals and humans is required, without guarantee of approval by the regulatory entities.
- Millions (or billions) of dollars and ~5-15 years are required for the whole process.
- A large share of the profit generated by the pharmaceutical industries comes from only a few drugs.
- Patent expiry narrows the profitability range of drugs and pushes the “me too” drug concept

The drug discovery pipeline/ funnel

Sun, Duxin, et al. *Acta Pharmaceutica Sinica B* 12.7 (2022): 3049-3062.

Drug Discovery & Development

Drugs are expensive

JAMA | Original Investigation

Estimated Research and Development Investment Needed to Bring a New Medicine to Market, 2009-2018

Olivier J. Wouters, PhD; Martin McKee, MD, DSc; Jeroen Luyten, PhD

Mean Cost:
\$1.3 billion

Table 4. Mean And Median Expected Research and Development Expenditure on New Therapeutic Agents Approved by the US Food and Drug Administration (2009-2018) by Therapeutic Area

Therapeutic Area ^a	Sample Size	Expenditure in US\$, Millions (95% CI) ^b	
		Median	Mean
Antineoplastic and immunomodulating agents	20	2771.6 (2051.8-5366.2)	4461.2 (3114.0-6001.3)
Alimentary tract and metabolism	15	1217.6 (613.9-1792.4)	1430.3 (920.8-2078.7)
Nervous system	8	765.9 (323.0-1473.5)	1076.9 (508.7-1847.1)
Antiinfectives for systemic use	5	1259.9 (265.9-2128.3)	1297.2 (672.5-1858.5)
Dermatologicals	4	747.4	1998.3
Cardiovascular system	3	339.4	1152.4
Musculoskeletal system	3	1052.6	937.3
Blood and blood-forming organs	2	793.0	793.0
Sensory organs	2	1302.8	1302.8
Other ^c	1	1121.0	1121.0

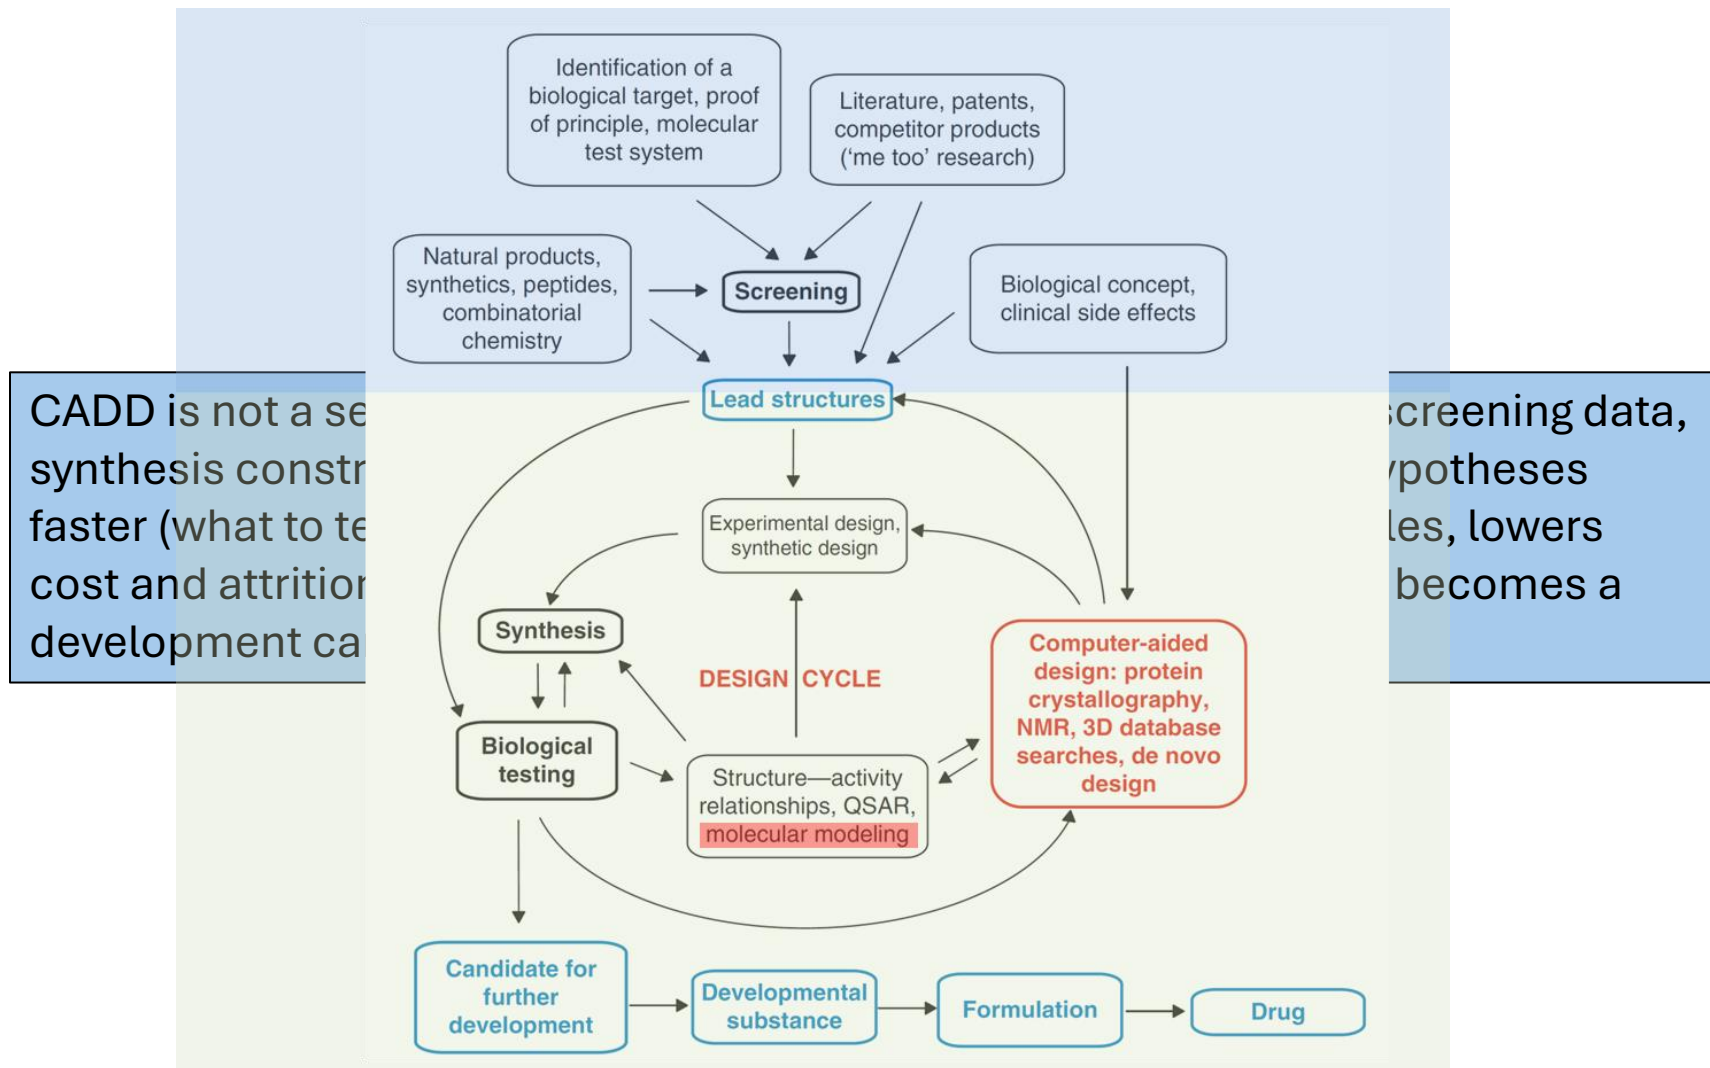

Wouters(2020) *J.Am.Medical Assoc.*, 323:884

Where does CADD fit ?

- Target modeling → homology modeling, molecular dynamics
- Hit discovery → virtual screening, de novo design, similarity search
- Lead optimization → QSAR, free energy calculations, QM calculations
- ADME/Tox → in silico property prediction, predictors, machine learning / AI

CADD does not replace the experiments – *it guides them !*

The Drug Design cycle and CADD

Structure-based *versus* ligand-based DD

- **Structure-based Drug Design (SBDD):** relies knowledge of the 3D *structure* of the *target* and ligand to predict and optimize activity (docking, virtual screening, molecular dynamics)
- **Ligand-based Drug Design (LBDD):** relies on *similarity* to known actives to find and expand new actives (chemical similarity, descriptors, pharmacophores, QSAR)

Examples:

- **SBDD:** designing kinase inhibitors from crystal structures
- **LBDD:** predicting analogues for GPCR ligands when no receptor structure is known

Core computational techniques for DD

- **Molecular modelling** – building and visualizing molecules
- **Molecular Mechanics** – molecular energetics (approximate) and conformation search
- **Quantum Chemistry** – electrostatics, reactivity, bond energy, rigorous molecular energetics
- **Molecular dynamics** – target flexibility, induced fit
- **Docking & Virtual screening** – binding prediction and energetics
- **Machine Learning and AI** – predict properties, automated discovery, generate new molecules

Modelling flow

Key databases in CADD

- **PDB** – protein structures
- **Uniprot** – *annotated* protein sequences
- **PubChem** – small molecules + targets
- **ChEMBL** – small molecules + bioactivity data
- **DrugBank** – drugs + targets + pharmacology
- **ZINC** – virtual screening libraries (very large collections)
- **PDBind** – protein-ligand complexes and K_i / K_d
- **CCDB** – small molecule (crystal structures)

1995

HIV protease inhibitors – CADD contribute

- **Accelerated the design process** - Rather than random screening, researchers could rationally design molecules
- **Provided visualization** - Scientists could "see" how molecules might interact with the target
- **Enabled prediction** - They could predict binding modes and relative affinities before synthesis
- **Guided optimization** - Structural data from crystallography combined with modelling guided improvements

Oseltamivir (Tamiflu)

- Neuraminidase cleaves sialic acid from cell surface to allow flu virus particles to leave the host cell

- Zanamivir is too polar – poor oral bioavailability, taken by inhalation
- Oseltamivir can be taken via the oral route
- Both are *transition state analogues*
- Scaffold hopping** to explore related, but chemically distinct entities.

Oseltamivir (Tamiflu) – CADD contribute

- Structure-based design using X-ray crystallography
- Molecular modeling and visualization
- Iterative design cycles
- More emphasis on **scaffold replacement** rather than substrate mimicry
- Significant focus on **predicting pharmacokinetic properties** (absorption, distribution)
- Computational chemistry helped identify which molecular features were essential vs. dispensable
- Greater emphasis on optimizing **drug-like properties** computationally

Representing Chemical Structures

Representation Name	Representation of Caffeine
Common Name	Caffeine
Synonyms	Guaranine
	Methyltheobromine
	1,3,7-Trimethylxanthine
	Theine
Empirical Formula	C ₈ H ₁₀ N ₄ O ₂
IUPAC Name	1,3,7-trimethylpurine-2,6-dione
CAS Registry Number	58-08-2
ChEMBL ID	CHEMBL113
Wiswesser Line Notation (WLN)	T56 BN DN FNVNVJ B F H
SMILES	<chem>CN1C=NC2=C1C(=O)N(C(=O)N2C)C</chem>
Aromatic SMILES	<chem>CN1C(=O)N(C)c2ncn(C)2C1=O</chem>
InChI	1S/C8H10N4O2/c1-10-4-9-6- 5(10)7(13)12(3)8(14)11(6)2/h4H,1-3H3
InChIKey	RYYVLZVUVIJVGH-UHFFFAOYSA-N
Topography	
Surface	

Visualizing Chemical Structures

- a** – dreiding model
- b** – ball-and-stick
- c** – vdW (CPK)
- d** – molecular surface
- e** – surface potential
- f** – HOMO orbitals

Descriptors in chemical space

Finding the essential chemical descriptors (dimensionality reduction), classifying, filtering, selecting.

Machine learning-methods

Lipinski's rule of 5

Peripheral drugs

84% Ro5 compliant
53% inside the Golden Triangle
70% have CNS MPO score > 4

CNS drugs

92% Ro5 compliant
77% inside the Golden Triangle
70% have CNS MPO score > 4

Searching through chemical space

Scaffold - core structure or framework of a molecule that forms the central backbone to which various functional groups or substituents are attached

Scaffold hopping - Guided search through chemical space.

Molecular docking

- Molecular docking can produce results similar to high-throughput screening (HTS)
- Requires knowledge of ligand and target structures

HTS

Docking

Computational pharmacophore screening

- **SBS** – pharmacophore derived from the structure of the binding site
- **LBS** – pharmacophore is derived from the structure of a known ligand

Structure-based screening (SBS)

Ligand-based screening (LBS)

Molecular conformation is important

- Single conformations obtained from chemical databases don't tell the whole story!
- Molecular simulation methods can be used to explore the space of possible conformations and find **low-energy** conformations

Molecule docks in the “right” conformation

Systematic Conformational Search

- Exhaustive incremental dihedral rotation search

Single conformation

Scanning Conformational Space

Multiple conformations

Sequence/structure analysis of targets

- Sequence analysis can reveal patterns characteristic of ligand binding and mutations affect function or stability
- Molecular dynamics (MD) studies of the HIV protease reveal the dynamics of the ligand-free protein and effect of mutations on flexibility

HIV protease

- A** – Residues near bound inhibitor
- B** – Mutations leading to resistance
- C** – Mutations can affect flexibility
- D** – Dynamics of ligand free protein (studied by *MD simulations*)

Simulating the dynamics of molecules

- Capturing the dynamic aspect of ligand and target structure is often crucial to predict binding
- Molecular dynamics (MD) simulations predict the evolution of conformation with time.

MD simulation shows wide movement of Phe121 residue, enlarging the binding pocket of the receptor

Benzodiazepine-like inhibitor

The open conformation can accommodate ligands with extended functional groups, like the red group of the benzodiazepine-like inhibitor,

Bind free energy by MD simulations

- Estimation of the binding potency of a ligand is a most important computational task
- Molecular dynamics (MD) simulations can estimate both **relative** and **absolute** binding free energies (ΔG or $\Delta \Delta G$ of binding).

$$K_d = \frac{[R][L]}{[RL]}$$

$$\Delta G = RT \ln K_d$$

a)

b)

Drug Descriptors and QSAR

- Ligand molecules can be represented by **molecule descriptors** and **fingerprints**
- These molecule-dependent parameters can be used to fit QSAR models or to *train* Machine Learning models

ChemDes system – generation of fingerprints and descriptors

Train a machine learning model on experimental IC₅₀ data

Hansch Equation

Example: Adrenergic blocking activity of β-halo-β-arylamines

$$\text{Log} \left(\frac{1}{C} \right) = 1.22 \pi - 1.59 \sigma + 7.89$$

Conclusions:

- Activity increases if π is +ve (i.e. hydrophobic substituents)
- Activity increases if σ is negative (i.e. e-donating substituents)

Machine learning and AI

- Machine learning (ML) models are **trained** on experimental data (activity, toxicity, IC50, logP, etc)
- After learning, ML models can be used to:
 - Classification (eg: Toxic / non-Toxic)
 - Property prediction (eg: IC50, logP)
 - Generation of new compounds (eg: new structures or scaffolds with affinity to specific targets)
 - Reactivity prediction (eg: CYP metabolism)
 - Binding poses (hard)
 - Protein structure prediction (AlphaFold)
 - ...much more....
